

A CONTROL SYSTEM FOR
A TURBO-CHARGED DIESEL AIRCRAFT ENGINE

5

ABSTRACT OF THE DISCLOSURE

10 In the control system for a turbo-charged diesel
aircraft engine, a target value for a fuel injection
amount is determined by the stroke of a throttle lever. A
boost compensator determines the maximum limit for the
fuel injection amount in accordance with the boost
15 pressure of the engine in order to suppress the formation
of exhaust smoke. The actual fuel injection amount is
set at the target value or the maximum limit whichever is
smaller. An electronic control unit (ECU) calculates an
increase rate of the stroke of the throttle lever based
20 on an output of the stroke sensor disposed near the
throttle lever. The ECU determines that the current
operating condition of the aircraft requires a rapid
increase in the engine output power when the increase
rate of the stroke is larger than a predetermined value
and increases the maximum limit determined by the boost
25 compensator.
